

FERAM CELL WITH INTERNAL OXYGEN SOURCE
AND METHOD OF OXYGEN RELEASE

DESCRIPTION

Field of the Invention

The present invention relates to ferroelectric (FE) capacitors and to a method of fabricating the same. More specifically, the present invention relates to an integrated ferroelectric capacitor/CMOS structure which comprises at least a ferroelectric material, a pair of electrodes in contact with opposite surfaces of the ferroelectric material, wherein the electrodes do not decompose at deposition or subsequent processing, and an oxygen source layer in contact with at least one of said electrodes, said oxygen source layer comprising a metal oxide which at least partially decomposes during deposition and/or subsequent processing.

Background of the Prior Art

Recent advances in ferroelectric (FE) materials have led to renewed interest in their use for memory device applications. One of the primary advantages of ferroelectric materials is that they can provide non-

5 volatile memory. Another advantage is that ferroelectric materials have a very high dielectric constant (on the order of 20 or above) associated therewith. The number of applications requiring inexpensive non-volatile memory is rapidly expanding. A breakthrough which would enable cheap
10 integration of non-volatile memory would accelerate this trend.

Ferroelectric materials pose several integration challenges which have not yet been solved. In particular,
15 ferroelectric materials typically require oxygen annealing after deposition of the material in order to operate as a storage medium. This annealing step is preferably carried out after the top electrode of the capacitor and before the BEOL (back end of the line) films are in place. The
20 annealing not only serves to improve the quality of the electrode/ferroelectric interface, but it also repairs damage to the ferroelectric material that may arise from any high energy processing steps, such as an anisotropic etching for top electrode and/or ferroelectric patterning.
25 Acceptable device characteristics may further require additional oxygen annealing after BEOL processing, to remove oxygen vacancies created in the ferroelectric material during exposure to hydrogen in steps such as dielectric deposition and forming gas anneals.

30 The inability of oxygen to permeate the numerous BEOL films limits the effectiveness of anneals towards the end of the

5 wafer fabrication process. In addition, oxygen anneals are typically incompatible with BEOL materials such as Cu, which is easily oxidized, and organic low-k dielectrics, which react with oxygen to form volatiles. These factors present a problem since anneals greatly improve the storage
10 characteristics of the ferroelectric material.

There is thus a great need for developing a method which can be employed in fabricating an integrated ferroelectric/CMOS structure which has improved storage
15 characteristics. Such a method should obviate or mitigate the need for high temperature oxygen anneals at late stages in processing when the BEOL layers are in place. Any method developed should achieve this goal despite difficulties in getting oxygen to permeate through the
20 various BEOL film layers without oxidation damage to any of the BEOL layers.

Summary of the Invention

25 One object of the present invention is to provide an integrated ferroelectric/CMOS structure which has improved storage characteristics.

Another object of the present invention is to provide an
30 integrated ferroelectric/CMOS structure wherein sufficient oxygen is present in the integrated structure to obviate or

5 mitigate the need for high temperature oxygen anneals at late stages in processing.

A further object of the present invention is to provide a method of manufacturing an integrated ferroelectric/CMOS
10 structure wherein sufficient oxygen is present therein such that the storage characteristics of the integrated structure is improved upon at least partial release of said oxygen.

15 A still further object of the present invention is to provide a simple method of fabricating an integrated ferroelectric/CMOS structure which can be used with CMOS technology as well as BEOL technology.

20 These and other objects and advantages can be obtained in the present invention for both ferroelectric capacitors and non-ferroelectric capacitors containing high-epsilon ($\epsilon \geq 20$) dielectric materials by utilizing an oxygen source layer in the integrated structure. This oxygen source layer is
25 typically a metal oxide which will at least partially decompose during ferroelectric/high-epsilon material deposition and/or subsequent device processing to release oxygen into the integrated structure, with consequent improvement of device storage characteristics. The
30 decomposition and/or oxygen release temperature, T_d , of the oxygen source layer is preferably low enough to allow substantial oxygen release without damage to the layers in

5 the integrated structure (i.e., Td preferably $\leq 700^{\circ}\text{C}$), yet
high enough to insure that complete oxygen release does not
occur during BEOL fabrication (i.e., Td preferably ≥ 350 -
400 $^{\circ}\text{C}$). The aforementioned subsequent device processing
may additionally include a post-BEOL anneal specifically
10 directed toward releasing the desired amount of oxygen from
the oxygen source layer.

In one aspect of the present invention, a ferroelectric
capacitor is provided which comprises:

15 a conductive electrode layer;

a ferroelectric layer disposed on said conductive electrode
layer;

20 a conductive counterelectrode layer formed on said
ferroelectric layer; and

an at least partially decomposed oxygen source layer
proximate to one of said conductive electrode layers.

25

The above ferroelectric capacitor may also comprise one or
more additional conductive electrode layers. These
additional electrode layers can be positioned either above
or below the conductive electrode layers of the inventive
capacitor. One or more oxygen-impermeable dielectric
30 overlayers can be formed above the uppermost layer of the

5 storage capacitor of the present invention. The conductive electrodes of the ferroelectric capacitor of the present invention may be independently patterned or unpatterned.

The ferroelectric capacitor described above forms part of
10 the integrated ferroelectric/CMOS structure of the present invention. Specifically, the integrated FE/CMOS structure of the present invention comprises:

a CMOS structure having at least one transistor region;
15 a ferroelectric capacitor formed on said CMOS structure, said ferroelectric capacitor comprising a conductive electrode layer, a ferroelectric layer disposed on said conductive electrode layer, a conductive counterelectrode layer formed on said ferroelectric layer, and an at least
20 partially decomposed oxygen source layer proximate to one of said conductive electrode layers; and
wiring levels formed on said ferroelectric capacitor.

25 In another aspect of the present invention, a method is provided for fabricating an integrated ferroelectric capacitor/CMOS structure. In accordance with this aspect of the present invention, the method comprises the steps
30 of:

- 5 (a) forming at least one complementary metal oxide semiconductor (CMOS) device on a semiconductor wafer;
- (b) forming a ferroelectric capacitor over said CMOS device, said ferroelectric capacitor comprising at least
10 one oxygen source layer in proximity to a conductive electrode layer, said oxygen source layer being capable of at least partially decomposing at temperatures below 700°C;
- (c) forming wiring levels on said ferroelectric capacitor
15 at temperatures below 450°C; and
- (d) optionally annealing the structure at a temperature above 300°C so as to at least partially decompose the oxygen source layer releasing oxygen in the ferroelectric
20 capacitor.

While the above aspects of the invention have been described for ferroelectric capacitors only, it should be understood that the scope of the present invention includes the application of the same inventive aspects and elements
25 to non-ferroelectric capacitors containing high-epsilon dielectric materials.

Brief Description of the Drawings

5 Figs. 1(a)-(c) show the various processing steps that are employed in one embodiment of the present invention for fabricating an integrated FE capacitor/CMOS structure.

Figs. 2(a)-(f) shows cross-sectional views of other
10 ferroelectric capacitors of the present invention wherein the oxygen source layer is depicted in different portions of the structure.

Detailed Description of the Invention

15 The present invention will now be described in greater detail by referring to the drawings that accompany the present application. It should be noted that in the accompanying drawings like reference numerals are used for
20 describing like and corresponding elements of the drawings.

Reference is made to Figs. 1(a)-(c) which illustrate one embodiment of the method of the present invention. In this embodiment, the oxygen source layer is shown on top of the
25 conductive counterelectrode layer. Although illustration is given for this specific embodiment, the method of the present invention also contemplates variations in the same which will be described hereinbelow.

30 Fig. 1(a) illustrates the initial structure of the present invention which includes a portion of a CMOS structure which may contain additional elements besides those

5 illustrated that are well known to those skilled in the art. Specifically, the structure shown in Fig. 1(a) comprises a semiconductor substrate 10 having diffusion regions 12, i.e. diffused portions of the bitlines formed in the surface thereof. On top of the semiconductor
10 substrate there is shown a transistor region 14 which is in contact with the diffusion regions. The structure shown in Fig. 1(a) further comprises conductive layers 16 which are formed in a dielectric layer 18.

15 The structure shown in Fig. 1(a) is composed of conventional materials that are well known to those skilled in the art and it is fabricated using techniques that are also well known in the art. For example, semiconductor substrate 10 is composed of any semiconducting material
20 including, but not limited to: Si, Ge, SiGe, GaAs, InAs, InP, all other III/V semiconducting compounds and organic semiconductors. The semiconductor substrate may be doped or undoped. The diffusion regions may contain p or n type dopants.

25 Transistor region 14 is comprised of a conventional gate stack which includes a layer of gate insulator such as SiO_2 formed on the surface of the semiconductor substrate and a layer of polysilicon or other gate conductor formed on the
30 gate insulator. A salicide layer may be formed on top of the polysilicon or gate conductor. Transistor region 14 may also include sidewall isolation regions as well as

5 other conventional components well known to those skilled
in the art. For simplicity, the various elements of the
transistor are not shown in the drawings, but are
nevertheless intended to be included in transistor region
14.

10

Conductive layers 16 comprise conductive materials known to
the art such as metals, conductive nitrides, conductive
metal silicon nitrides, conductive silicides, conductive
oxides and mixtures or multilayers thereof. Exemplary
15 conductive materials include: Cu, W, Al, polysilicon, TiN,
Ta, TaN, Ti and WSi_x. Conductive layers 16 may comprise a
number of metal lines and vias which can be composed of the
same or different conductive material. For simplicity, the
drawings of the present invention show two vias and one
20 metal line.

Dielectric layer 18 is composed of any inorganic or organic
dielectric material known in the art including, but not
limited to: SiO₂, Si₃N₄, SiCOH, diamond, diamond-like
25 carbon (i.e. amorphous C), paralyene polymers, polyimides,
silicon-containing polymers and other suitable dielectric
materials. Dielectric layer 18 may be composed of the same
material, as is depicted in Fig. 1(a), or different
dielectric materials can be employed. When different
30 dielectric materials are used, a barrier layer, not shown
in the drawings, may be formed between each successive
dielectric layer. The optional barrier layer is composed

5 of conventional materials including, but not limited to:
 SiO_2 , Al_2O_3 , TiO_2 , Si_3N_4 , SiO_xN_y and Ta_2O_5 .

As stated above, the structure shown in Fig. 1(a) is
fabricated using conventional processing steps which are
10 well known to those skilled in the art including:
semiconductor device fabrication and back end of the line
(BEOL) processing. For example, the CMOS device shown in
Fig. 1(a) can be fabricated by forming the transistor
region on the surface of the semiconductor substrate, i.e.
15 growing a gate insulator, depositing a gate conductor on
said gate insulator and thereafter patterning those layers
to provide the transistor region. The diffusion regions
can then be formed using conventional ion implantation and
annealing.

20 Conductive layers 16 of the CMOS structure shown in Fig.
1(a) are then typically formed by: depositing a first
dielectric layer on the surface of the semiconductor
structure, opening a via in the dielectric layer, filling
25 the via with a conductive material, planarizing the
structure using conventional planarization techniques such
as chemical-mechanical polishing or grinding, and then
forming a metal line by depositing a second dielectric
layer, opening a trench in the second dielectric layer,
30 filling the trench with a conductive material and
planarization.

5 In accordance with the present invention, a ferroelectric capacitor is formed on the CMOS structure shown in Fig. 1(a). This step of the present invention is shown in Fig. 1(b). The ferroelectric capacitor may be patterned, non-patterned or contain a mixture of patterned and non-patterned layers.

Specifically, a conductive electrode layer 20 is first formed on the surface of the CMOS structure so that it is in electrical contact with the conductive layers of the CMOS structure. The conductive electrode layer 20 is the bottom electrode of the ferroelectric capacitor of the present invention.

Suitable conductive electrode materials that can be used in the present invention as conductive electrode layer 20 include, but are not limited to: noble metals such as Pt, Pd, Ir, Rh, Os, Au, Ag, and Ru; noble metal oxides such as PtO_x , IrO_x , PdO_x , RhO_x , OsO_x , AuO_x , AgO_x and RuO_x ; conductive oxides such as SrRuO_3 , LaSrCoO_3 and $\text{YBa}_2\text{Cu}_3\text{O}_7$; mixtures and multilayers thereof. The noble metals and/or oxides may be crystalline or in an amorphous form. The conductive electrode layer of the capacitor may be unpatterned, or patterned using conventional lithography and RIE.

Electrode layer 20 may further include one or more layers of conductive barrier materials selected from the group containing metal nitrides (for example TiN , TaN , WN , TaAlN ,

5 TiAlN), metal silicon nitrides (for example, TaSiN, TiSiN),
metal oxides, and metal oxynitrides.

After forming conductive electrode layer 20, which may
include planarization, the structure may optionally be
10 subjected to an appropriate surface treatment step.
Suitable surface treatments that may optionally be employed
in the present invention include: oxidation by plasma
ashing, thermal oxidation, surface chemical treatments and
application of a thin metal oxide layer by chemical
15 solution deposition (CSD), chemical vapor deposition (CVD)
or physical vapor deposition (PVD).

In accordance with the present invention, a ferroelectric
layer 22 is formed on the surface of conductive electrode
20 layer 20. While layer 22 is described here and below as
ferroelectric, it should be understood that layer 22 may
comprise a non-ferroelectric high-epsilon ($\epsilon \geq 20$) dielectric
material without deviating from the intents of this
invention. Ferroelectric layer 22 may be patterned or
25 unpatterned. When patterned the ferroelectric film may be
surrounded by a dielectric layer to ensure a planar
structure. A suitable anneal may be performed after
forming ferroelectric layer 22 to achieve desired
ferroelectric properties. Typically, such an anneal is
30 carried out at a temperature of about 600°C or above.

5 The ferroelectric layer or non-ferroelectric high-epsilon
layer that is employed in the present invention is a
dielectric material which has a dielectric constant of 20
or above. This includes a crystalline, polycrystalline or
amorphous high dielectric constant material. Preferred
10 ferroelectric materials employed as layer 22 include, but
are not limited to: the perovskite-type oxides, compounds
containing pyrochlore structures such as $\text{Cd}_2\text{Nb}_2\text{O}_7$, potassium
dihydrogen phosphates, phosphates of rubidium, cesium or
arsenic and other like ferroelectric materials.
15 Combinations of these ferroelectric materials or
multilayers are also contemplated herein. High-epsilon
materials may also be employed in the present invention as
the high dielectric constant ferroelectric layer. The high
dielectric material may display a spontaneous electric
20 polarization (for NVRAM) or not (for DRAM).

Of the aforementioned ferroelectric materials, it is highly
preferred that ferroelectric layer 22 of the present
invention be composed of a perovskite-type oxide. The term
25 "perovskite-type oxide" is used herein to denote a material
which includes at least one acidic oxide containing at
least one metal from Group IVB (Ti, Zr or Hf), VB (V, Nb or
Ta), VIB (Cr, Mo or W), VIIB (Mn or Re), IIIA (Al, Ga or
In) or IB (Cu, Ag or Au) of the Periodic Table of Elements
30 (CAS version) and at least one additional cation having a
positive formal charge of from about 1 to about 3. Such
perovskite-type oxides typically have the basic formula:

5 ABO_3 wherein A is one of the above mentioned cations, and B is one of the above mentioned metals which forms the acidic oxide.

Suitable perovskite-type oxides include, but are not
10 limited to: titanate-based ferroelectrics, manganate-based materials, cuprate-based materials, tungsten bronze-type niobates, tantalates, or titanates, and bismuth layered-tantalates, niobates or titanates. Of these perovskite-type oxides, it is preferred to use strontium bismuth
15 tantalate, strontium bismuth niobate, bismuth titanate, strontium bismuth tantalate niobate, lead zirconate titanate, lead lanthanum zirconate titanate, and compositions of these materials modified by the incorporation of dopants as the ferroelectric material.

20 A conductive counterelectrode layer 24 is then formed on the surface of ferroelectric layer 22. The counterelectrode layer which forms the top electrode of the storage capacitor of the present invention may be formed of
25 the same or different conductive material as conductive electrode layer 20. The counterelectrode layer may also be patterned or unpatterned.

The final layer shown in Fig. 1(b) is an oxygen source
30 layer 26 which is capable of at least partially decomposing below 700°C so as to release sufficient oxygen into the

5 structure to cause improvements in the storage characteristics of the ferroelectric capacitor. Preferably the oxygen source layer comprises a conductive metal oxide having the formula MO_x , wherein M is selected from the group consisting of a noble metal such as Pd, Pt, 10 Ir, Rh, Ru and Os, a non-noble metal, and mixtures or alloys of these metals. The oxygen source layer may further be a mixture or multilayer combination of these MO_x oxides alone or with one or more elemental additives selected from the group containing noble metals, non-noble 15 metals, nitrogen (N), semiconductors such as Si, Ge, C, and B. Mixtures may be uniform in composition or graded in composition.

The value of x in MO_x may range from about 0.03 to about 3. 20 MO_x materials having low values of x would typically have M-like structures distorted by interstitial oxygen incorporation; MO_x materials having high values of x would typically have metal-oxide-like lattice structures and M-O bonding. The oxygen source layer may be crystalline or 25 amorphous, or a mixture of crystalline and amorphous phases. Crystalline oxygen source layers may include: PdO, PtO_2 , PtO, Pt_3O_4 , and IrO_2 . Oxygen source layers comprising metal- MO_x mixtures include: PtO_x mixed with Pt.

30 Noble metal alloy oxides (or mixtures of noble metal oxides) comprising two or more component oxides having different decomposition characteristics are particularly

5 preferred oxygen source layers, since their decomposition characteristics can be tuned by changing the relative proportions of the component oxides. Examples of such oxygen source layers include: $\text{Ir}_y\text{Pt}_z\text{O}_x$ or $\text{Pd}_y\text{Pt}_z\text{O}_x$, in which a relatively stable noble metal oxide (IrO_2 or PdO) having
10 a high decomposition temperature is combined with a relatively unstable noble metal oxide (PtO_x) having a low decomposition temperature to provide a material with an intermediate decomposition temperature.

15 The oxygen source layer may be patterned or unpatterned, and is preferably conductive, to facilitate electrical connection to the top electrode. However, an insulating oxide may be used for oxygen source if contact holes are provided therein.

20 It is noted that in Fig. 1(b), layers 20, 22, 24 and 26 represent one possible configuration of the ferroelectric capacitor of the present invention. Other possible configurations are shown in Figs. 2(a)-(f). In these
25 figures, reference numerals 20, 22, 24 and 26 are as defined above. Reference numeral 28 represents an optional conductive electrode layer that may be present in the present invention which may comprise any of the electrode and barrier materials listed previously. Common to each of
30 these figures is that the oxygen source material is formed in proximity to one of the electrode layers of the ferroelectric capacitor of the present invention. Fig.

5 2(f) shows a three dimensional (non-planar) ferroelectric capacitor that can be also be formed using the method of the present invention. Optional sidewall spacers may be present on patterned layers 20 and 26 of the structure shown in Fig. 2(f).

10

The various layers which make-up the ferroelectric capacitor of the present invention are formed using conventional deposition processes well known to those skilled in the art. For example, layers 20, 24, 26 and
15 optional layer 28 may be formed by chemical vapor deposition (CVD), plasma-assisted CVD, electron beam evaporation, thermal evaporation, thermal oxidation, sputtering, reactive sputtering, plating and other like deposition techniques alone or in combination. After
20 deposition of each layer, the structure may optionally be planarized using conventional techniques such as chemical-mechanical polishing. Patterning may also be performed using conventional lithography and reactive ion etching.

25 Ferroelectric material layer 22 is also formed using conventional deposition techniques well known to those skilled in the art including, but not limited to: chemical solution deposition (CSD), sol gel, metal-organic decomposition, spin coating, sputtering, reactive
30 sputtering, metal-organic chemical vapor deposition, physical vapor deposition, plasma-assisted chemical vapor deposition, pulsed laser deposition, chemical vapor

5 deposition, evaporation and like deposition techniques. A high temperature anneal may need to be performed at this time to obtain desired ferroelectric properties.

After forming the structure shown in Fig. 1(b), which may
10 include patterning of all the capacitor layers in one step or a plurality of steps, various wiring levels may be formed on top of the structure. This step of the present invention including the optional patterning step is illustrated by Fig. 1(c). When patterning is performed the
15 patterned capacitor, i.e. layers 20, 22, 24 26 and optional 28 may be encapsulated by an optional dielectric layer (not shown) to protect the ferroelectric from out-diffusion of oxygen species and in-diffusion of hydrogen species. The optional dielectric encapsulant layer would typically be an
20 oxide, nitride or oxynitride, such as SiO_2 , SiN_x , SiO_xN_y , TiO_2 , Ta_2O_5 , or Al_2O_3 .

The wiring levels are formed by first forming dielectric material 30 on the structure and thereafter forming
25 conductive layers 32 therein using BEOL processing techniques that preferably operate well below the decomposition temperature of the oxygen source layer, for example, at or below 400°C . Dielectric layer 30 may be composed of the same or different dielectric material as
30 layer 18; likewise conducting layers 32 may be composed of the same or different materials as conducting layers 16.

5 The at least partial decomposition of the oxygen source layer may occur concurrently with other steps in processing such as ferroelectric/high-epsilon material deposition, top electrode deposition, optional encapsulant deposition, and BEOL processing. The at least partial decomposition of the
10 oxygen source layer may also take place during device operation (at a very slow rate) or during a post-BEOL anneal specifically directed toward releasing the desired amount of oxygen from the oxygen source layer into the ferroelectric capacitor to improve the storage
15 characteristics of the same. The post-BEOL anneal may be conducted in a substantially inert gas atmosphere, e.g. vacuum, He, Ar and N₂, that can be optionally mixed with an oxidizing gas such as O₂, steam, O₃, N₂O or H₂O₂. Preferred annealing temperatures that can be employed in the present
20 invention are from about 350° to about 700°C, with from about 350° to about 500°C being more highly preferred. Typically, annealing is carried out for a time period of from about 1 minute to about 4 hours, with from about 1 minute to about 10 minutes being more highly preferred.
25 The annealing step may be carried out using a single ramp cycle or multiple ramp and soak cycles can also be used.

While the present invention has been particularly shown and described with respect to preferred embodiments thereof, it
30 will be understood by those skilled in the art that the foregoing and other changes in form and detail may be made

5 without departing from the spirit and scope of the present invention.
